Cheat Sheet: Python Data Structures Part-2

Dictionaries

Package/Method	Description	Code Example
		Example:
Creating a Dictionary	A dictionary is a built-in data type that represents a collection of key-value pairs. Dictionaries are enclosed in curly braces {}.	 1. 1 2. 2 1. dict_name = {} #Creates an empty dictionary 2. person = { "name": "John", "age": 30, "city": "New York"}
Accessing Values	You can access the values in a dictionary using their	<pre>Copied! Syntax: 1. 1 1. Value = dict_name["key_name"] Copied! Example: 1. 1 2. 2 1. name = person["name"]</pre>
		<pre>2. age = person["age"] Copied! Syntax: 1. 1 1. dict_name[key] = value</pre>
Add or modify	Inserts a new key-value pair into the dictionary. If the key already exists, the value will be updated; otherwise, a new entry is created.	Copied! Example: 1. 1 2. 2 1. person["Country"] = "USA" # A new entry will be created. 2. person["city"] = "Chicago" # Update the existing value for the same key
del	Removes the specified key-value pair from the dictionary.	Copied! Syntax: 1. 1 1. del dict_name[key] Copied! Example: 1. 1 1. del person["Country"]
update()	The update() method merges the provided dictionary into the existing dictionary, adding or updating key-value	<pre>Syntax: 1. 1 1. dict_name.update({key: value}) Copied! Example:</pre>
clear()	The clear() method empties the dictionary, removing all key-value pairs within it. After this operation, the dictionary is still accessible and can be used further.	1. 1 1. dict_name.clear()
		Copied! Example: 1. 1 1. grades.clear()

```
Example:
                                                                                 1. 1
                    You can check for the existence of a key in a dictionary
key existence

    if "name" in person:
    print("Name exists in the dictionary.")

                    using the in keyword
                                                                              Copied!
                                                                              Syntax:
                                                                                 1. 1
                                                                                 1. new_dict = dict_name.copy()
                                                                               Copied!
                    Creates a shallow copy of the dictionary. The new
                    dictionary contains the same key-value pairs as the
copy()
                                                                              Example:
                    original, but they remain distinct objects in memory.
                                                                                 1. new_person = person.copy()
2. new_person = dict(person) # another way to create a copy of dictionary
                                                                               Copied!
                                                                              Syntax:
                                                                                 1. 1
                                                                                 1. keys_list = list(dict_name.keys())
                    Retrieves all keys from the dictionary and converts them
                                                                              Copied!
                    into a list. Useful for iterating or processing keys using
keys()
                    list methods.
                                                                              Example:
                                                                                 1. 1
                                                                                 1. person_keys = list(person.keys())
                                                                               Copied!
                                                                              Syntax:
                                                                                 1. 1
                                                                                 1. values_list = list(dict_name.values())
                    Extracts all values from the dictionary and converts them Copied!
                    into a list. This list can be used for further processing or
values()
                                                                              Example:
                    analysis.
                                                                                 1. person_values = list(person.values())
                                                                               Copied!
                                                                              Syntax:
                                                                                 1. 1
                                                                                 1. items_list = list(dict_name.items())
                    Retrieves all key-value pairs as tuples and converts them
                                                                              Copied!
items()
                    into a list of tuples. Each tuple consists of a key and its
                                                                              Example:
                    corresponding value.
                                                                                 1. info = list(person.items())
                                                                              Copied!
Sets
```

Copied!

Package/Method	Description	Code Example
		Syntax:
		1. 1
add()		<pre>1. set_name.add(element)</pre>
	Elements can be added to a set using the 'add()' method. Duplicates are automatically removed, as sets only store unique values.	Copied!
		Example:
		1. 1
		 fruits.add("mango")
clear()	The `clear()` method removes all elements from the set, resulting in an empty set. It updates the set in-place.	Copied!
		Syntax:
		1. 1
		 set_name.clear()

```
Example:
                                                                                                             1. 1
                                                                                                             1. fruits.clear()
                                                                                                          Copied!
                                                                                                          Syntax:
                                                                                                             1. 1
                                                                                                             1. new_set = set_name.copy()
                                                                                                           Copied!
                  The 'copy()' method creates a shallow copy of the set. Any modifications to the copy
copy()
                  won't affect the original set.
                                                                                                          Example:
                                                                                                             1. 1
                                                                                                             1. new_fruits = fruits.copy()
                                                                                                           Copied!
                                                                                                          Example:
                                                                                                             2. 2
                  A set is an unordered collection of unique elements. Sets are enclosed in curly braces
Defining Sets
                                                                                                             1. empty_set = set() #Creating an Empty
2. Set fruits = {"apple", "banana", "orange"}
                   `{}`. They are useful for storing distinct values and performing set operations.
                                                                                                          Copied!
                                                                                                          Syntax:

    set_name.discard(element)

                                                                                                          Copied!
                  Use the 'discard()' method to remove a specific element from the set. Ignores if the
discard()
                  element is not found.
                                                                                                          Example:
                                                                                                             1. 1

    fruits.discard("apple")

                                                                                                           Copied!
                                                                                                          Syntax:
                                                                                                             1. 1
                                                                                                             1. is_subset = set1.issubset(set2)
                                                                                                          Copied!
                  The 'issubset()' method checks if the current set is a subset of another set. It returns
issubset()
                  True if all elements of the current set are present in the other set, otherwise False.
                                                                                                          Example:
                                                                                                             1. is_subset = fruits.issubset(colors)
                                                                                                          Copied!
                                                                                                          Syntax:
                                                                                                          is superset = set1.issuperset(set2)
                  The 'issuperset()' method checks if the current set is a superset of another set. It
                                                                                                          Example:
issuperset()
                  returns True if all elements of the other set are present in the current set, otherwise
                  False.
                                                                                                             1. 1
                                                                                                             1. is_superset = colors.issuperset(fruits)
                                                                                                           Copied!
                                                                                                          Syntax:
                                                                                                             1. removed_element = set_name.pop()
                                                                                                          Copied!
                  The 'pop()' method removes and returns an arbitrary element from the set. It raises a
                  'KeyError' if the set is empty. Use this method to remove elements when the order
pop()
                                                                                                          Example:
                  doesn't matter.
                                                                                                             1. removed_fruit = fruits.pop()
                                                                                                           Copied!
                  Use the 'remove()' method to remove a specific element from the set. Raises a
remove()
                                                                                                          Syntax:
                   'KeyError' if the element is not found.
                                                                                                             1. 1

    set name.remove(element)

                                                                                                           Copied!
```

Copied!

```
    fruits.remove("banana")
